1. What Makes Agent UX Different

Traditional UX is built around **commands → predictable outcomes.** A user clicks a button; something defined happens. Agentic AI breaks this model: the user states an intent, and an autonomous system *reasons, plans, chooses tools, and acts* across multiple steps — often asynchronously, often irreversibly.

This creates a new set of design problems that traditional UX principles don't fully address:

Traditional UX	Agentic UX
User controls every step	Agent controls steps; user controls goals
Predictable, deterministic output	Probabilistic, variable output
Errors are system errors	Errors include hallucinations & overreach
Feedback is immediate	Feedback spans minutes, sessions, or days
Single interaction loop	Multi-step, interrupted, async workflows
Fixed interface	Potentially generative interface

2. The Foundational Design Principles

2.1 The Seven Core Principles

1. Clarity of Intent Ambiguity doesn't stay small in autonomous systems — it multiplies. Interfaces must help users articulate not just goals but *constraints, exceptions, and success criteria* before agents begin. This means designing structured intent frameworks, not just prompt boxes.

2. Transparency as Primary Affordance Users should never have to guess what an agent is doing or why. Transparency means:

- Showing which tools were called and what they returned
- Surfacing confidence levels on outputs
- Explaining reasoning in human language: *"Because you said X, I did Y"*

- Revealing what data the agent used

3. Perceived Control (Psychological Requirement) Even controls users rarely touch are essential. The *presence* of override, pause, and undo mechanisms makes the entire system feel trustworthy. Remove them and users resist or abandon agents entirely, even when performance is good.

4. Emotional Safety Through Feedback Silent processing is anxiety-inducing. Invisible progress creates the sensation of being at the mercy of an opaque system. Status updates like *"Searching three databases — step 2 of 5"* are not niceties; they're psychological infrastructure.

5. Calibrated Confidence Agents must communicate how sure they are. Research shows binary indicators (high/low confidence) outperform numeric percentages in real-world testing. The design response must match confidence levels:

- **High (90%+):** Auto-proceed + visible indicator
- **Medium (60–89%):** Surface as suggestion, require confirmation
- **Low (<60%):** Pause, request clarification, offer alternatives

6. Ethical Constraints as UI Features Ethics shouldn't live only in policy documents. They should be embedded as *visible, interactive design elements*: permission flows, scope warnings, audit logs, and accessible kill switches.

7. Collaboration Over Replacement Agent interfaces should preserve human judgment at inflection points. The "checkpoint moment" — where the system pauses to confirm — is a design primitive, not a UX tax.

---

3. The Autonomy Spectrum: A Core Design Decision

Level	Mode	Behavior
1	Observe & Suggest	Notifications only, no action
2	Plan & Propose	Creates plan, waits for review
3	Act with Confirmation	Executes steps, final approval required
4	Act Autonomously	Background execution, notification after

Default to the lowest autonomy level users will tolerate for a given task type, then allow per-task-type escalation as trust is built.

---

4. Interaction Patterns Across the Lifecycle

4.1 Pre-Action Phase

Intent Preview Pattern — Before executing, show a plain-language summary of the planned action sequence. Give users three explicit choices: *Proceed / Edit Plan / Handle it Myself*.

Plan-and-Execute UI — Display proposed steps as a vertical list. Steps should remain editable even after execution starts.

Goal-First Onboarding — Prove value on the first interaction by building a workflow instantly, not by explaining features.

4.2 In-Action Phase

Live Status Communication

- Bad: *"Processing..."*
- Good: *"Searching your codebase — found 3 matching files"*
- Good: *"Step 2 of 5 — Drafting email based on your calendar context"*

Tool-Use Disclosure — Surface which external systems were called and what they returned.

Explainable Rationale — Ground explanations in user inputs: *"You mentioned preferring shorter emails, so I kept this under 150 words."*

Confidence Signals — Green for high confidence, yellow for uncertainty, dotted borders for low-confidence outputs.

4.3 Post-Action Phase

Action Audit & Undo — Chronological log of all agent-initiated actions with time-limited reversal. Auto-flag if >5% of actions are reverted.

Escalation Pathway — Target 5–15% escalation frequency; >90% post-escalation recovery indicates healthy design.

---

5. Trust Architecture

5.1 The Three Trust Failure Modes

Over-trust (Automation Bias) – Users rubber-stamp decisions. Fix: add intentional friction at high-stakes checkpoints.

Under-trust (Excessive Skepticism) – Users constantly override even well-performing agents. Fix: show reasoning, surface confidence, provide track records.

Miscalibrated Trust – Users trust in the wrong domains. Fix: explicit scope boundaries and visible confidence degradation at domain edges.

5.2 Trust-Building Interaction Design

- Declare the agent's nature and purpose at interaction start
- Make data collection practices explicit: what's stored, how long, who can access it
- Let users customize behavior (tone, detail level, when to interrupt vs. proceed)
- Show the agent's accuracy track record over time
- Design empathic error responses: acknowledge → correct → support → review

---

6. Human-in-the-Loop (HITL) Design

6.1 When to Insert HITL

Trigger	Example
High-stakes, irreversible actions	Sending an email, deleting records, making a purchase
Policy exceptions	Loan approvals, access grants, contract terms
Ambiguous intent	Unclear user instruction, conflicting constraints
Low-confidence output	Agent confidence <60%
Domain boundaries	Agent operating outside its training scope
Regulated industries	Healthcare, finance, legal

6.2 Designing the HITL Moment

- **Summarize context**, not raw data
- **State the specific question** clearly
- **Show the consequence** of each choice
- **Provide relevant history**
- **Never auto-approve** based on countdown timers or passive acceptance

Treat human reviewers as collaborators, not bottlenecks. Clunky HITL interfaces create governance theater where reviewers approve without reading.

---

7. Multi-Step Task Interface Patterns

7.1 Separate Conversation from Activity Streams

Chat threads cannot effectively track autonomous workflows that run asynchronously, involve parallel sub-agents, or span hours or sessions. Dedicate a separate panel to show *what was done / what is running / what is blocked / what is next*.

7.2 Progress Visibility Architecture

Event	UI Response
RUN_STARTED	Show start indicator, ETA if available
STEP_STARTED	Update current step, pulse animation
STEP_FINISHED	Checkmark, show result
RUN_FINISHED	Summary card, action prompts
RUN_ERROR	Error state, recovery options

7.3 Resume & Interruption Handling

On return users need a clear anchor. Implement:

- Progress chips inline in conversation threads
- Visible step trackers in side panels

- Session continuity summaries: *"While you were away: 3 tasks completed, 1 needs your review"*

7.4 Mission Control Pattern

For power users: a visual Kanban-style board where each card represents a task assigned to an agent, with live feeds, priorities, dependencies, and agent attribution visible at a glance.

---

8. Error Handling & Graceful Failure

8.1 The Three Error Categories

Predictable Errors – Agent shows uncertainty. Surface it, ask for clarification, offer alternatives.

Edge Case Failures – System produces output without knowing it's wrong. Graceful degradation: Full AI → Simplified → Rule-based → Human handoff.

Silent Failures – Most dangerous. Agent is confidently wrong. Use inline citations, source disclosure, and verification prompts on high-stakes outputs.

8.2 Error Message Design

Structure every error as three parts:

1. **What happened** (specific)
2. **Why it happened** (honest self-assessment)
3. **What to try next** (concrete, actionable)

- **Bad:** *"An error occurred. Please try again."*
- **Good:** *"I couldn't find matching records in Salesforce – the filter may be too narrow. Try removing the date range restriction, or view all 847 records unfiltered."*

8.3 Recovery Path Design

Failure Type	Primary Recovery	Secondary Recovery
Ambiguous input	Ask clarifying questions	Show examples of valid inputs
Tool failure	Retry with explanation	Suggest alternative approach

Failure Type	Primary Recovery	Secondary Recovery
Out-of-scope request	Declare limitation clearly	Offer closest in-scope alternative
Low confidence output	Flag uncertainty, request verification	Escalate to human
Catastrophic / irreversible	Undo log, restore prior state	Human support escalation

---

9. Conversational UI Design Principles

Chat is good for: exploratory tasks, simple Q&A, short-horizon interactions.

Chat is bad for: long-running autonomous tasks, structured approvals, multi-agent orchestration, audit trails.

Intent-Based Interaction – Users declare the result; the system determines the procedure.

Proactive Nudges – Surface next-best actions without waiting to be asked, but silence when consistently ignored.

Memory Surfacing – Show the agent's persistent context without noise. Let users correct what the agent knows about them.

---

10. Mental Models & User Psychology

10.1 The Mental Model Problem

Users carry pre-existing – mostly wrong – mental models of what AI can do. Interface design is the primary tool for shaping accurate ones.

Design for accurate mental models by:

- Showing reasoning, not just conclusions
- Declaring capability boundaries explicitly
- Making confidence visible and calibrated
- Communicating failure modes honestly

10.2 Cognitive Load Management

- **Progressive disclosure:** Summary first, depth on demand
- **Chunked workflows:** Break long tasks into digestible phases
- **Reduce decision fatigue:** Batch low-stakes approvals
- **Design for neurodiversity:** Reducing cognitive load benefits everyone

---

11. Real-World Product Design Analysis

ChatGPT / GPT-4 Agents

- **Good:** Inline confidence hedging, tool use disclosure
- **Gap:** No persistent task tracking, poor multi-session continuity

Claude (Anthropic)

- **Good:** Explicit capability declaration, Projects for persistent context, Claude Code's transparent agentic loop
- **Gap:** Web UI less suited for long-horizon task management

GitHub Copilot Workspace / Agent Mode

- Deep IDE integration with plan visibility and diff previews before code changes
- Good HITL: PR review as a natural checkpoint — 1.2M PRs/month at scale

Microsoft 365 Copilot

- Side-panel integration preserving existing workflows
- Strong context awareness from calendar, email, and documents

Devin (Cognition Labs)

- Explicit planning + task-tracking structures before execution
- Visible state machine — users see the agent's current phase throughout

Intercom Fin

- Agent suggests replies; human approves before sending
- Clean low-friction HITL: approve or edit, not write from scratch

Notion AI Agents

- Agents work inside document/workspace context with natural embedded checkpoints

---

12. Emerging Patterns (2025–2026)

Generative UI – The interface itself is generated by the AI. Users state a goal; the agent builds an interactive dashboard on the fly.

Multimodal Interfaces – Seamless switching between chat, voice, screen sharing, and automated workflows. The modality matches the task.

Multi-Agent Coordination UI – Showing responsibility distribution across agent networks: swimlane views, agent-tagged activity logs, orchestrator dashboards.

Proactive / Ambient Agents – Operate in the background, surface at relevant moments. Key challenge: avoiding notification fatigue. "Nudging more than notifying."

AG-UI Protocol – Emerging standard defining lifecycle events as a shared language between agent backends and frontends.

---

13. Regulatory & Compliance Dimensions

Requirement	Design Response
Explainability (EU AI Act)	Rationale UI, decision trails
Human oversight	Mandatory HITL checkpoints for high-risk AI
Data transparency (GDPR)	In-context disclosure of data used
Right to contest	Undo, appeal, and correction mechanisms
Accessibility (EAA)	Cognitive load reduction, plain language, multimodal
Audit trail	Persistent action logs, exportable

---

14. Common Anti-Patterns to Avoid

Anti-Pattern	Problem	Fix
Black Box Launch	No visibility into agent decisions	Add rationale UI before shipping
Demo-Optimized Design	Only handles happy path	Design for ambiguity and partial results
Single-Agent Assumption	Designed for 1 agent; roadmap needs multi	Architect for agent attribution from day 1
Chat-Only Task Management	Long workflows buried in threads	Separate activity stream/panel
Auto-Accept Patterns	Countdown timers, pre-checked approvals	Require active confirmation for consequential actions
Technical Error Messages	Users see stack traces and confidence scores	Human-language errors with next steps
Rubber-Stamp HITL	Clunky review with no context	Design HITL as a collaboration moment
Confidence Omission	Outputs with no certainty signal	Always attach confidence to consequential outputs

15. Design Process Recommendations

1. Run trust calibration studies – Interview users about their mental model. Gaps predict failure points.

2. Simulate misbehavior in testing – Deliberately break the agent and watch how users recover.

3. Build the Governance Structure

- Legal/Compliance: Define operational boundaries
- Product: Maintain Agent Risk Register + autonomy policies
- UX Research: Trust calibration + mental model testing

- Engineering: Logging, undo infrastructure, rationale generation
- Support: Surface real-world failure patterns

4. Phased Rollout

- Phase 1: Intent Preview + Action Audit (Suggest/Propose only)
- Phase 2: Autonomy Dial + Explainable Rationale (Act with Confirmation)
- Phase 3: Full autonomous features for pre-approved, low-risk task types

---

16. The 10 Things That Matter Most

1. **Intent first, execution second** — show and confirm the plan before acting
2. **Confidence is a UI element** — surface it consistently, make it calibrated
3. **Separate conversation from activity streams** — chat can't track long-running tasks
4. **Progressive autonomy** — start narrow, expand based on trust built
5. **HITL is a feature, not a tax** — design the checkpoint as a collaboration moment
6. **Three-part error messages** — what, why, what next
7. **Undo is non-negotiable** — time-limited reversal for all consequential actions
8. **Transparency = reasoning, not just output** — show the work
9. **Proactive status, not reactive queries** — tell users before they ask
10. **Design for mental model accuracy** — users with wrong models will mis-trust or over-trust
